**Background:** WHO grade I meningiomas usually have an indolent course, while high-grade (grades II to III) tumors are associated with a more aggressive natural course.

Objective: To investigate clinical predictors of WHO grade, subtype, and atypical features of meningiomas.

Material and Method: Correlations between clinical variables and WHO grades, meningioma subtypes, atypical features of tumor, brain invasion, degree of connective tissue content, and microscopic calcification were analyzed.

Results: Of 233 meningiomas, 196 (84.1%) and 37 (15.9%) were WHO grade I and II, respectively. There were no WHO grade III tumors in the present study. Factors associated with a possibility of WHO grade II meningioma included younger age (p=0.025), larger tumor size (p=0.005), peritumoral brain edema (p=0.001), and isosignal intensity of tumor on T2WI (p=0.011) and FLAIR image (p<0.001). Hyposignal and hypersignal tumors on T2WI were correlated with transitional and meningothelial subtypes, respectively (p=0.001). Meningiomas with soft consistency were likely to be fibrous subtype and associated with a low level of connective tissue. Radiographic predictors of atypical histopathologic features were presence of cystic component, peritumoral edema, bony erosion and absence of CFS cleft between tumor and brain, and homogeneous enhancement of tumor on T2WI. Tumor isosignal intensity on T2WI and FLAIR images could forecast the appearance of atypical features and brain invasion in histopathology. Small size, spinal location, and hyposignal intensity of tumors on T2WI were correlated with dense microscopic calcification.

**Conclusion:** Various clinical factors can be used to predict high-grade meningioma, tumor subtype, and microscopic atypical features - all of which are useful in tumor management.

Keywords: Meningioma, WHO grades, Subtypes, Atypical features, Connective tissue content, Calcification

J Med Assoc Thai 2017; 100 (Suppl. 3): S122-S132 Full text. e-Journal: http://www.jmatonline.com

Meningioma is the most common benign primary tumor of the central nervous system<sup>(1)</sup>. Tumors can be categorized histopathologically into World Health Organization (WHO) grades I, II, or III<sup>(2)</sup>. Of these, WHO grade I meningiomas are benign and most commonly found. Meningioma can be treated with surgery, external beam radiation, or a combination of these two treatments<sup>(3)</sup>. Meningiomas with WHO grade II or III histology are regarded as high-grade meningiomas which have a higher risk of recurrence following treatment and are associated with lower overall survival<sup>(3-5)</sup>. Pathological criteria for diagnosing

high-grade meningioma are histological appearances and atypical features, including small cell formation, hypercellularity, sheet-like growth, necrosis, prominent nucleoli and mitosis, and brain invasion<sup>(2)</sup>. A number of meningiomas are classified as WHO grade I, but they have some components of atypical features that do not fulfil the criteria of high-grade meningioma.

This study set forth to investigate the clinical factors that correlate with atypical histopathological features of meningioma. These predictors may be helpful in the pre-operative or intra-operative recognition of high-grade tumors, facilitating their exclusion from wait-and-see therapy or radiation treatment alone.

### Material and Method Study design

Cross-sectional study.

#### **Population**

All patients with intracranial or spinal meningiomas who underwent tumor resection at our institute from January 2007 to December 2011 were enrolled. All recruited cases had meningiomas originating from the virgin sites that had never been operated upon or treated by radiation. Clinical, neuroimaging, and intra-operative data were collected and analyzed. In all cases, histologic sections were reviewed by a neuropathologist (PC). Tumors were graded according to WHO classification. The protocol for this study was approved by Siriraj Institutional Review Board (SIRB), Faculty of Medicine Siriraj Hospital, Mahidol University, Thailand.

#### Data collection

Collected data comprised gender, age, duration of neurologic symptoms before surgery, tumor location, tumor characteristics on neuroimaging studies, and intraoperative tumor consistency. Clinical data were obtained from outpatient and inpatient records. Features on neuroimaging studies included tumor calcification on non-contrast enhanced computerized tomography (NCECT), tumor size, evidence of vasogenic brain edema, cystic component within the tumor, hyperostosis or bony erosion of the tumor base, en plaque appearance, cerebrospinal fluid (CSF) cleft between the tumor and brain, and signal intensity of meningioma on T1-weighted imaging (T1WI), T2weighted imaging (T2WI), and fluid-attenuated inversion recovery (FLAIR) imaging. Tumor signal intensity on MRI sequences was stratified into hypersignal, isosignal, and hyposignal intensities, when compared to that of neural gray matter. We also studied pattern of tumor enhancement (homogeneous or heterogeneous) on contrast-enhanced computerized

tomography (CECT) and T1WI after injection of contrast media.

Intra-operative tumor consistency was obtained by operating neurosurgeons that used the grading system developed and reported in our previous study<sup>(6)</sup> (Table 1). Tumor grades and subtypes were classified using WHO criteria for classification of meningioma<sup>(2)</sup>. In cases that atypical features including small cell formation, hypercellularity, necrosis, prominent nucleoli, mitosis, and brain invasion were present (Fig. 1), each criteria was recorded. Degree of connective tissue content and calcification within the tumors were evaluated. Degree of connective tissue content was graded according to percentage of overall tumor section area as follows: low (<30%), moderate (30 to 60%), and high (>60%) (Fig. 2A-C). Degree of calcification was classified according to the 3 following levels: no calcification, low calcification (presence of calcification <50% of overall area), and high calcification (presence of calcification >50% of overall area) (Fig. 2D-F). Some data were unavailable in a number of cases; as such, the number of cases (n) for each individual parameter varied.

#### Statistical analysis

The data set was analyzed using the Statistical Package for the Social Sciences (SPSS) version 17.0 (SPSS, Inc., Chicago, IL, USA). One-way ANOVA was used to compare age and tumor size between groups. Pearson's Chi-square test and Fisher's exact test were used to investigate correlations between variables and pathological features. Data are presented as number or mean  $\pm$  SD. Strength of association was evaluated and presented as odds ratio (OR) and 95% confidence interval (95% CI). The statistically significant level was defined as p<0.05.

 $\textbf{Table 1.} \ \, \text{Classification of intraoperative meningioma consistency based on effectiveness of tumor resection performed using conventional neurosurgical tools and methods {}^{(6)}$ 

Grade	Consistency	Description
I	Soft	Meningioma can be removed using suction cannula for more than 80% of resected tumor volume
II	Intermediate	Meningioma can be removed using suction cannula for less than 80% of resected tumor volume <u>OR</u> Meningioma can be removed using ultrasonic aspirator for more than 80% of resected tumor volume
III	Hard	Meningioma cannot be removed using suction cannula $\underline{OR}$ Meningioma can be removed using ultrasonic aspirator for less than 80% of resected tumor volume $\underline{OR}$ Sharp surgical instrument, such as scalpel, surgical scissors, or loop monopolar electrocau tery, is required for tumor resection

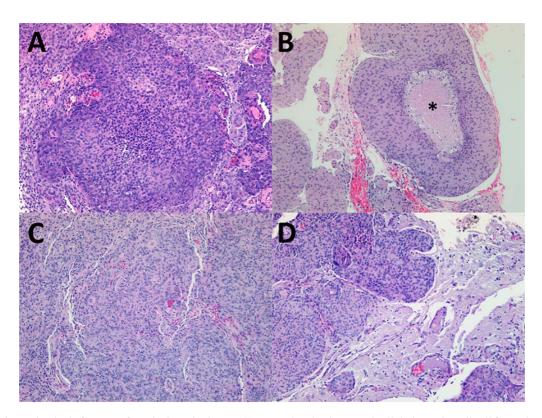

Fig. 1 Histologic features of atypical meningioma; (A) tumor showing increased cellularity and small cell formation with high nucleus/cytoplasm ratio (center); (B) spontaneous micronecrosis (asterisk); (C) prominent round nucleoli in numerous tumor cells; (D) brain invasion as tongue-like projection of tumor cells into brain parenchyma without intervening leptomeninge (hematoxylin and eosin stain, x100).

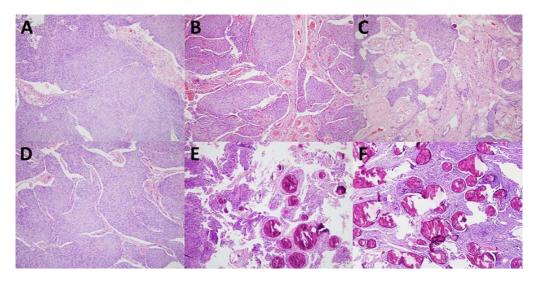

Fig. 2 Degree of connective tissue content (A-C) and calcification (D-F) of meningiomas; (A) low connective tissue content (<30% of HPF); (B) moderate connective tissue content (30 to 60% of HPF); (C) high connective tissue content (>60% of HPF); (D) no calcification; (E) low calcification (presence of calcification <50% of HPF); (F) high calcification (presence of calcification >50% of HPF).

#### **Results**

#### Demographic characteristics

Two hundred and twenty-three meningiomas were enrolled into the study. There were 199 (85.4%) females and 34 (14.6%) males, with a mean age of  $50.7\pm12.8$  years (range: 12-85). The most common location was sphenoid ridge (32 cases, 13.7%), followed by cerebral convexity (28 cases, 12%) and anterior clinoid process (27 cases, 11.6%) (Table 2). Mean tumor size was  $4.3\pm1.8$  cm (range:  $0.8\pm10$ ).

For histopathology, WHO grade I and II meningiomas were 196 (84.1%) and 37 (15.9%), respectively (Table 3). No WHO grade III meningiomas were identified in this study. The most common pathological subtype was meningothelial meningioma. Tumors that did not completely satisfy WHO grade II meningioma criteria were diagnosed as WHO grade I meningioma. Atypical features were found in both WHO grade I and II meningiomas. Cases with atypical features who met the diagnostic criteria of atypical meningioma were diagnosed as atypical meningioma. Meningiomas showing brain invasion were classified as WHO grade II meningioma, brain-invasive subtype<sup>(2)</sup>. From 233 studied cases, atypical features were identified, as follows: small cell formation (43 cases, 18.5%), hypercellularity (45 cases, 19.3%), necrosis (31 cases, 13.3%), prominent nucleoli (11 cases, 4.7%), mitosis >4 per HPF (2 cases, 0.9%), and no cases with sheet-like growth pattern. Brain invasive pattern was found in 19 (8.2%) of total cases, accounting for 51.4% of WHO grade II tumors.

From the correlation analysis between collected parameters and WHO grades and meningioma subtypes, we made the following observations (Table 4):

Mean age of WHO grade II group (46.4 years) was significantly younger than that of patients with WHO grade I tumors (51.5 years) (p = 0.025).

Mean tumor size of WHO grade II tumors  $(5.1\pm1.5 \text{ cm})$  was significantly larger than that of WHO grade I meningiomas  $(4.1\pm1.8 \text{ cm})$  (p=0.005).

Tumors with peritumoral vasogenic edema were 5.8 times more likely to be WHO grade II meningiomas than tumors without vasogenic edema (95% CI: 1.95-17.51; p = 0.001).

Tumors showing isosignal intensity on T2WI and FLAIR imaging were more likely to be grade II than I (p = 0.011), whereas hypersignal meningiomas on both MRI sequences were more likely to be grade I than II (p < 0.001).

Table 2. Tumor location

Tumor location	Number (%)
Supratentorial	166 (71.2)
Sphenoid ridge	32 (13.7)

other than meningothelial subtype. In contrast, hypersignal tumors on T2WI were more likely to be meningothelial subtype than other subtypes (p = 0.010).

Tumors with grade I consistency were significantly correlated with fibrous meningioma, rather than other subtypes. Grade II consistency meningiomas were more likely to be meningothelial, transitional, or subtypes other than fibrous variance (p = 0.005).

Regarding relationships between atypical features of meningioma and collected variables, the following associations were observed (Table 5):

Larger tumors were correlated with presence of small cell formation (p<0.001), necrosis (p = 0.002), and prominent nucleoli (p = 0.006).

Meningiomas with cystic component on neuroimaging were likely to exhibit small cell formation (p=0.004), necrosis (p=0.031), and prominent nucleoli (p=0.005).

Tumors having peritumoral vasogenic edema were significantly associated with small cell formation (p = 0.044) and hypercellularity (p = 0.003).

Small cell formation and necrosis were correlated with tumors eliciting radiographic bony destruction (p = 0.049 and p = 0.049, respectively).

Meningiomas without necrosis were significantly correlated with tumors showing CSF cleft between tumor and brain on neuroimaging (p = 0.023).

Isosignal tumors in FLAIR imaging were likely to display small cell formation, necrosis, and hypercellularity, whereas hypersignal tumors were likely to be absent of those features (p = 0.021, p = 0.043, and p < 0.001, respectively).

Isosignal tumors were likely to have hypercellularity on T2WI imaging, while hypersignal tumors were likely to have no hypercellularity (p = 0.005).

Tumors presenting homogeneous enhancement on T1WI imaging were likely to have small cell formation and hypercellularity. In contrast, meningiomas with heterogeneous enhancement were likely to be absent of both features (p<0.001 and p<0.001, respectively).

Regarding brain invasion, degree of connective tissue content, and calcification, we observed the following (Table 6):

Isosignal tumors on T2WI imaging were significantly likely to have brain invasion (p = 0.043). In addition, meningiomas showing isosignal intensity on FLAIR imaging were significantly correlated with

brain invasion, whereas hypersignal intensity tumors were likely to have no brain invasion (p = 0.017).

Hyposignal tumors on FLAIR imaging were correlated with higher connective tissue content (p = 0.004).

Meningiomas with consistency grade I were more likely to have a low degree of connective tissue content (p = 0.027).

Mean age of patients with tumors absent microscopic calcification tended to be younger than patients with tumors showing microscopic calcification (p=0.004).

Mean size of tumors without calcification in histopathology (4.5 cm) was significantly larger than that of tumors with high calcification (2.6 cm) (p=0.046).

Meningiomas involving the spine were likely to have a high degree of calcification (p<0.001).

Presence of tumor calcification on neuroimaging was correlated with presence of calcification in histopathology (p = 0.008).

Hyposignal tumors on T2WI imaging were correlated with high degree of calcification in histopathology. Hypersignal tumors, in contrast, were likely to have either no calcification or low degree of calcification (p<0.001).

Isosignal tumors on FLAIR imaging were correlated with low degree of microscopic calcification, whereas hypersignal tumors were likely to have no calcification (p<0.010).

#### Discussion

Meningioma is a common neoplasm that develops in the neuraxis. Management of this tumor varies and is dependent upon several factors. WHO grade I tumors usually have a stable size or grow gradually over several years, whereas WHO grade II and III meningiomas have a higher risk of rapid growth. Differentiation between WHO grade I and high-grade meningiomas is useful for decision making in the management of these tumors. WHO grade I meningiomas found incidentally or with small-size can be treated by wait-and-see therapy or external beam radiation, but tumors with high-grade properties should be treated more aggressively.

#### Demographic characteristics

Meningiomas are 2 to 4 times more common in females than in males<sup>(7,8)</sup>. In our study, female to male tumor ratio was up to more than 5:1. WHO grades II and III are found in 21 to 37.8% of cases<sup>(5,9-11)</sup>. Zhou et al reported a proportion of WHO grade II meningioma

\* Indicates statistically significant correlation (p<0.05); Data are presented as number or mean ± SD. Degree of connective tissue content: low (<30% per HPF); moderate (30-60% of HPF); and, high (>50% of HPF)

of HPF).

of 21.3%<sup>(8)</sup>. In the present study, we found WHO grade II meningioma in 15.9% of patients. This proportion is slightly less than any grade II proportion ever reported.

#### Prediction of WHO grades of meningioma

Previous studies showed that male, younger age, larger tumor size, irregular shape, lateral and non-skull base locations, and peritumoral vasogenic edema correlated with high-grade (WHO grades II to III) meningioma<sup>(8,12,13)</sup>. Because our series had no cases with WHO grade III, we conclude that younger age, larger tumor size, peritumoral vasogenic edema, and tumors demonstrating isosignal intensity on T2WI and FLAIR imaging can be used to predict a possibility of WHO grade II meningioma.

# Prediction of histopathologic subtypes of meningioma

In the present study, hyposignal tumors on T2WI imaging were likely to be transitional subtype, whereas meningothelial meningiomas were associated with hypersignal intensity. These correlations were identical to those of previous studies(14-17). In studies conducted prior to the implementation of WHO 2007 classification of central nervous system tumors, some studies found tumors exhibiting hard consistency to be directly correlated with fibroblastic subtype<sup>(18,19)</sup>. In addition to focusing on tumor component, we also focused on connective tissue component. To our knowledge, no previous studies have investigated correlation between tumor consistency and amount of connective tissue. From our findings, tumors with soft consistency were likely to be fibrous subtype, whereas firmer tumors were likely to be meningothelial, transitional, or other variations. Moreover, soft consistency tumors were likely to have a lower amount of connective tissue component. Subgroup analysis showed that meningioma subtypes and amount of connective tissue were not confounding factors. We, therefore, believe that meningioma consistency is constituted from both components. Furthermore, our study showed that hyposignal meningiomas on FLAIR imaging contained a higher amount of connective tissue component. This finding, according to our review of previous studies, has not been mentioned in any previous reports.

# Prediction of atypical features and meningioma with brain invasion

Based on our review of the literature, no prior

study has investigated direct correlation between clinical parameters and atypical features of meningioma, which are the criteria for diagnosis of high-grade meningioma. From our findings, we can conclude that presence of cystic component, peritumoral vasogenic edema, bony erosion on neuroimaging, isosignal intensity of tumor on T2WI and FLAIR imaging, and homogeneous enhancement of tumor on T1WI can be used as predictors of an individual atypical feature. We also found that absence of CFS cleft between the tumor and brain can reliably predict necrosis. Brain invasion is a unique criterion for diagnosing WHO grade II meningioma. Importantly, we found that isosignal intensity tumor on T2WI and FLAIR imaging can also predict this feature.

#### Predictors correlating with microscopic calcification

Calcification visualized on neuroimaging was found to be directly concordant with microscopic calcification. Hyposignal tumors on T2WI imaging had more microscopic calcification. On the contrary, meningiomas with hypersignal intensity on T2WI and FLAIR imaging had less calcification in histopathology. Meningiomas situated in the supratentorial and spinal regions tended to have microscopic calcification. Based on our review of the literature, this is the first study to report this finding.

#### Conclusion

Younger age, peritumoral brain edema, and isosignal intensity tumors on T2W and FLAIR imaging can be utilized for predicting the possibility of WHO grade II meningioma. Existence of cystic component, peritumoral brain edema, and bony erosion in pre-operative neuroimaging can be independently used to forecast occurrence of some atypical histopathological features. Meningiomas showing hyposignal intensity on T2WI tend to be transitional subtype, whereas hypersignal tumors portend meningothelial variance. Intra-operative soft consistency can be used to predict the possibility of fibrous subtype, and is associated with a low level of connective tissue in histopathology.

### What is already known from this topic?

Several factors, including male, younger age, larger tumor size, irregular shape, lateral and non-skull base locations, and peritumoral vasogenic edema, are associated with high-grade (WHO grades II to III) meningiomas. Meningiomas with hard consistency tend to be fibroblastic subtype. To date, no previous

study has investigated correlation between tumor consistency and amount of connective tissue, correlation between clinical parameters and atypical histopathological features, and predictors of microscopic calcification.

#### What this study adds?

Factors correlated with a possibility of WHO grade II meningioma are young age, larger tumor size, peritumoral edema and isosignal intensity of tumor on T2WI and FLAIR image. Hyposignal tumors on T2WI are associated with transitional meningioma, whereas hypersignal tumors on T2WI are correlated with meningothelial subtypes. Meningiomas with soft consistency tend to be fibrous subtype and tend to contain a low level of connective tissue. Radiographic predictors of atypical histopathologic features are presence of cystic component, peritumoral edema, bony erosion and absence of CFS cleft between tumor and brain, and homogeneous enhancement of tumor on T1WI. Radiographic predictors of atypical features include presence of cystic component, peritumoral edema, bony erosion and absence of CFS cleft between tumor and brain, and homogeneous enhancement of tumor on T1WI. Tumor isosignal intensity on T2WI and FLAIR image can predict appearance of atypical features and brain invasion in histopathology. Small size, spinal location, and hyposignal intensity of tumors on T2WI were correlated with dense microscopic calcification.

#### Potential conflicts of interest

None.

\_\_\_\_\_ ตัวพยากรณ์ทางคลินิกของระดับเนื้องอกตามการแบ่งขององค์การอนามัยโลก, ชนิดย<sup>่</sup>อยและลักษณะทางพยาธิวิทยาที่ผิดปกติ ของ meningioma

### อินธิรา ขัมภลิขิต, พรสุข ชื่นสุชน, บรรพต สิทธินามสุวรรณ

ภูมิหลัง: meningioma ระดับหนึ่งตามการแบงขององค์การอนามัยโลกมีการดำเนินโรคแบบค่อยเป็นค่อยไปในขณะที่ meningioma ระดับสองและสาม มีการดำเนินโรคที่รุ่นแรงมากกวา่

วัตถุประสงค์: เพื่อศึกษาตัวพยากรณ์ทางคลินิกของระดับเนื้องอกตามการแบงขององค์การอนามัยโลก, ชนิดย่อยและลักษณะทางพยาธิวิทยาที่ผิดปกติของ meningioma

วัสดุและวิธีการ: ทำการวิเคราะห<sup>์</sup>ความสัมพันธ์ระหว<sup>่</sup>างตัวแปรทางคลินิกกับระดับเนื้องอกตามการแบ<sup>่</sup>งขององค<sup>์</sup>การอนามัยโลก, ชนิดย<sup>่</sup>อย, ลักษณะทาง พยาธิวิทยาที่ผิดปกติ, ลักษณะที่เนื้องอกลามเข้าเนื้อสมอง, ปริมาณเนื้อเยื่อเกี่ยวพันและการมีแคลเซียมในเนื้องอก

ผลการศึกษา: จาก meningioma 233 ราย 196 ราย (ร้อยละ 84.1) เป็นระดับหนึ่งและ 37 ราย (ร้อยละ 15.9) เป็นเนื้องอกระดับสอง ไม่มีเนื้องอกระดับสามในงานวิจัยนี้ ปัจจัยที่มีความสัมพันธ์กับความเป็นไปได้ที่จะเป็น meningioma ระดับสอง ได้แก่ อายุน้อย (p = 0.025) เนื้องอก ขนาดใหญ่ (p = 0.005) กาวะสมองบวมรอบเนื้องอก (p = 0.001) และ meningioma ที่มีความเข้มต่ำกวาเนื้อสมองในการตรวจภาพแม่เหล็กไฟฟ้าของสมองชนิด T2W สัมพันธ์กับชนิดย่อย transitional และ meningioma ที่มีความเข้มสู่งกว่าเนื้อสมองในการตรวจภาพแม่เหล็กไฟฟ้าของสมองชนิด T2W สัมพันธ์กับชนิดย่อย meningothelial นอกจากนี้ยังพบว่า meningioma ที่มีความเข้มสู่งกว่าเนื้อสมองในการตรวจภาพแม่เหล็กไฟฟ้าของสมองชนิด T2W สัมพันธ์กับชนิดย่อย meningothelial นอกจากนี้ยังพบว่า meningioma ที่มีความเข้มส่วนกับเนื้องอกที่มีปริมาณด่ำ ด้วบงชี้ทางรังสีวิทยาของลักษณะที่ผิดปกดิของ meningioma ได้แก่ การพบสวนที่เป็นถุงน้ำในเนื้องอก กาวะสมองบวมรอบเนื้องอก พบการทำลายของกระดูกที่อยู่ใกล้เนื้องอก ไม่พบช่องน้ำหล่อสมองและใขสันหลังระหวางเนื้องอกกับสมองและเนื้องอก เป็นสีขาวเหมือนกันทั้งก้อนในการตรวจภาพแม่เหล็กไฟฟ้าของสมองชนิด T2W และ FLAIR มีความสัมพันธ์กับลักษณะผิดปกดิของเนื้องอก และลักษณะที่เนื้องอกลามเข้าเนื้อสมองในการตรวจภาพแม่เหล็กไฟฟ้าของสมองชนิด T2W และ FLAIR มีความสัมพันธ์กับลักษณะผิดปกดิของเนื้องอก และลักษณะที่เนื้องอกลามเข้าเนื้อสมองในการตรวจภาพแม่เหล็กไฟฟ้าของสมองชนิด T2W และ FLAIR มีความสัมพันธ์กับลักษณะผิดปกดิของเนื้องอกด่ำกว่า เนื้อสมอง ในการตรวจภาพแม่เหล็กไฟฟ้าของสมองชนิด T2W สัมพันธ์กับการพบแคลเชียมปริมาณมากในเนื้องอก

สรุป: สามารถใช้ปัจจัยทางคลินิกหลายอย<sup>่า</sup>งเพื่อชวยในการพยากรณ์ความเป็นไปได้ที่จะเป็น meningioma ระดับสองและสาม ชนิดย<sup>่</sup>อยและลักษณะ ผิดปกติของเนื้องอก ซึ่งข้อมูลเหล่านี้มีประโยชน์ในแง่การรักษาเนื้องอก
