Abstract

Objective : To conduct a hospital-based survey to assess women's attitude and acceptance towards menopause and hormone replacement therapy (HRT).

Method : The authors conducted a survey in women who visited the menopause clinic in 5 university and public hospitals in Bangkok. A group of 615 women who lived in those catchment areas and voluntarily cooperated in responding to a set of standardized questionnaires was randomly selected.

Results : Of the total respondents, 97.0 per cent were in the age range between 40-70 years, 51.7 per cent were in the peri- and postmenopausal period, 65.7 per cent believed that menopause is a natural change but some may need medical treatment, 53.9 per cent were current users of which the average duration of HRT use was 4.70 ± 3.36 years. The most common reasons for HRT initiation were osteoporosis, hot flashes, and vaginal dryness. The most common side effects found in the current users were breast pain, headache, and vaginal bleeding. Of all the current users, 43.2 per cent wanted to switch from HRT. Most of the respondents (95.4%) based their decision on the choices of treatment on medical advice. Of the total respondents, 62.0-74.7 per cent reported not having enough clear information on menopause and HRT.

Conclusion : According to the present study, most of the women regarded menopause as a natural change of life although some need treatment. The most common indications for HRT were osteoporosis, hot flashes and vaginal dryness. Nearly half of the current users wanted to switch from HRT. Most of the respondents based their treatment decision on medical advice.

Key word : Menopause, HRT, Attitude, Acceptance

One of the earliest evidence on the effects of sex hormones on reproductive organs seemed to begin in 1896 when an Austrian scientist, Emil Knauer, demonstrated that oophorectomy induced uterine atrophy. The action of sex hormones was confirmed by Joseph Halban in 1900 who showed that ovarian re-implantation prevented uterine atrophy. Attempts to isolate and identify key hormones from ovarian extract were of no avail until 1929 when an American scientist, Edward Doisy in parallel with a German scientist, Adolph Butenandt identified the first estrogen from the urine of pregnant women ie., estrone (E1). Finally, in 1935 MacCorQuodale isolated the most potent form of estrogen ie, estradiol (E2) from sow ovaries(1,2).

Estrogen has long been associated with menopausal changes and used as hormone replacement for relieving menopausal symptoms. In 1941, Albright and colleagues(3) demonstrated the association of estrogen deficiency and osteoporotic fracture. After which various studies confirmed the efficacy of hormone replacement therapy (HRT) for menopausal therapy.

In Thailand, "the menopause-boom" began after the 6th International Congress on the Menopause which was held in Bangkok in 1990. The use of HRT has increased since then(4,5). However, a nation-

wide survey conducted by a pharmaceutical company revealed that the overall HRT use rate was 3.0 per cent(6). This is comparable to Japan where the penetration rate is not more than 2.0 per cent. On the contrary, the reported percentage of women taking HRT in North America, Western Europe and Australia is over 30.0 per cent(7,8).

Before the official establishment of the first menopause clinic in Thailand in 1992, menopausal care was incorporated as part of the general gynecologic clinic. Less attention was paid to women's health during the climacteric which is considered to be a physiologic change. Nevertheless, some women suffered from menopausal symptoms while others were prone to long-term consequences of estrogen deficiency e.g., osteoporosis and fractures.

By 1992, the Ministry of Public Health of Thailand realized the importance of the health issue during the climacteric and officially established menopause clinics in government health centers throughout the country. Nowadays, hundreds of women each day seek menopausal care in menopause clinics in several public hospitals. It has been over 10 years since the first menopause clinic was officially opened. Therefore, the authors decided to conduct hospital-based surveys in 5 university and government hospitals to assess women's perception and attitude towards menopause and HRT in Bangkok.

METHOD

From January to March 2002, the authors conducted a survey in women aged more than 35 years, who visited the menopause clinic in 5 university and government hospitals i.e., Chulalongkorn University Hospital, Pramongkutklao Military Hospital, Police General Hospital, Somdej Prapinklao Hospital, and Nopparat Rajathanee Hospital. These centers are located in lower to middle socioeconomic areas. The target population was women who lived in those catchment areas. A group of 615 women who voluntarily cooperated by responding to a set of standardized questionnaires were randomly selected. Those who refused to fill up the questionnaires were illiterate or had visual difficulties. Most of the respondents completed the questionnaires but some did not answer all the questions.

The questionnaires consisted of a series of questions concerning demographic characteristics, knowledge and attitude towards menopause and HRT.

The contents and language were adapted for optimal understanding after a first pilot pretest was done. Descriptive statistics were used where appropriate.

RESULT

The characteristics of the studied population are shown in Table 1. Of the total respondents, 97.0 per cent were in the age range between 40-70 years, 51.7 per cent were in the peri- and postmenopausal period, and 19.0 per cent had undergone a hysterectomy with bilateral oophorectomy.

The respondents' attitude towards menopause is shown in Fig. 1-5 which revealed that 65.7 per cent believed that menopause is a natural change but some may need medical treatment, 73.7 per cent still had a positive relationship with their spouse, 42.0 per cent continued to have a good relationship with their offspring, 82.6-86.8 per cent had a good relationship with relatives and colleagues.

The respondents' acceptance on HRT is shown in Fig. 6 which revealed that 53.9 per cent

were current users of which the average duration of HRT use was 4.70 ± 3.36 years (range 1-25 years). For past users (21.4% of total respondents), the average duration of use was 1.81 ± 2.25 years (range 0-13 years). The indications for HRT in users (current and past users) are shown in Fig. 7-9, and the three most common indications were osteoporosis, hot flashes, and vaginal dryness.

The side effects which were reported by all of the current users are shown in Fig. 10-12 of which the three most common side effects found in severe and moderate groups were breast pain, headache, and vaginal bleeding. In addition, 43.2 per cent of all the current users wanted to switch from HRT for various reasons (Fig. 13) of which the most common concern was cancer phobia (42.9%).

The reasons for HRT discontinuation in past users are shown in Fig. 14. The side effects which caused HRT discontinuation among past users were breast pain, headache and vaginal bleeding (Fig. 15). New therapeutic options for past users included calcium supplement 88.5 per cent, exercise 76.9 per cent, non-HRT medication 30.8 per cent, and no treatment 19.2 per cent.

When asked about the decision on the choices of menopausal therapy, most of the respondents (95.4%) based their decision on medical advice (Fig. 16). Concerning the quality of information on menopause and HRT, most of the respondents (62.0-74.7%) were not able to obtain enough clear information.

DISCUSSION

In the present study, respondents' attitude towards menopause was not extreme. Most of the women believed that menopause was a physiologic change but some needed medical treatment. Most of the respondents believed there was no change in their relationship with their spouse, offspring, relatives and colleagues. This is similar to the attitude of other Asian women who consider menopause as a physiologic change and suffer less from menopausal transition compared to their Occidental counterparts^(7,9,10).

The results from the present survey revealed that more than half of menopause clinic visitors were current HRT users. This is different from a nationwide HRT study in 1998 by a pharmaceutical company which revealed that the prevalence of current users was only 3.0 per cent⁽⁶⁾. The difference is

probably due to the hospital-based nature of the present study compared to the community-based survey of the latter. As a matter of fact, people who suffer from menopausal symptoms or have high health awareness, tend to seek medical care compared to those who have fewer symptoms or are less concerned about menopausal health.

Nevertheless, due to the small sample size ($n = 400$) of the 1998-study, the 3.0 per cent prevalence of current users equals 8 cases. This is too small a number to make any analysis regarding women's attitude and acceptance towards HRT. Therefore, the authors decided to conduct a hospital-based survey in 5 hospitals which have well established menopause clinics and were willing to join the study. The authors expected to obtain a reasonable sample size of HRT users, so more details of women's attitude and acceptance on HRT could be gathered.

Regarding the reasons for HRT initiation in current users, it was found that the common indications were osteoporosis, hot flashes, vaginal dryness and skin problems, respectively. This was similar to the reported indications in past users after performing a subgroup analysis. The result showed that bone

indication was the most common reason for HRT initiation. This is probably due to the influence of physicians' attitude which has lately emphasized osteoporosis.

Almost half of the current users reported moderate to severe side effects from HRT. The most common complaints were breast pain, headache and vaginal bleeding. This is in conjunction with later information which revealed that almost half of the current users wanted to switch from HRT. The reasons were mainly based on the women's concern about cancer from the use of HRT and fear of hormone accumulation.

By the same token, the reasons for HRT discontinuation in past users were mainly related to HRT's safety aspects (cancer concern and HRT's side effects). In addition, the true reason for those who changed treatment from HRT (27.0% of past users) may stem from respondents' concern about the safety of prolonged use of hormone.

When asked about the decision on the choices of menopausal therapy, most of the respondents (95.4%) based their decision on medical advice. The others (7.9-22.8%) made their choices by using

information from leaflets and brochures, attending a health conference, newspapers, books and magazine, friends, and television and radio. However, only one-third of the respondents (25.6-38.0%) reported receiving enough clear information on menopause and HRT. In contrast, a survey in Taiwan⁽¹¹⁾ found that most of the women's knowledge of the menopause was obtained from reading material (43.0%) and friends (22.0%). Only 18.0 per cent revealed that the source of knowledge was from medical personnel. Moreover, 71.0 per cent of these women thought they should receive therapy.

As a matter of fact, HRT awareness and acceptance in this respondent group may not represent the attitude of Thai women nationwide. Nonetheless, it revealed opinions and problems on menopause and the use of HRT in a group of women living in Bangkok who sought medical care in their climac-

teric. Therefore, it is obvious that health education is needed to help women understand the changes during menopausal transition and the choices of therapeutic strategies. Health care providers must be knowledgeable and well trained to provide enough clear information to women prior and after the transition.

วัตถุประสงค์ : เพื่อศึกษาถึงทัศนคติและความยอมรับของสตรีต่อภาวะหมดประจำเดือนและการใช้ฮอร์โมนทดแทน

วิธีการ : คณะผู้วิจัยได้สำรวจสตรีที่มารับบริการที่คลินิกสตรีวัยหมดประจำเดือนในโรงพยาบาลมหาวิทยาลัยและโรงพยาบาล
สาธารณะ 5 แห่งในกรุงเทพมหานคร โดยสุ่มเลือกสตรีจำนวน 615 ราย ซึ่งมีที่อยู่อาศัยอยู่ใกล้เคียงโรงพยาบาลที่สำรวจและ
สมัครใจที่จะตอบแบบสอบถามมาตรฐาน

ผลการศึกษา : ร้อยละ 97.0 ของผู้ตอบแบบสอบถาม มีอายุระหว่าง 40-70 ปี ร้อยละ 51.7 อยู่ในวัยใกล้หมด
ประจำเดือนและวัยหลังหมดประจำเดือน ร้อยละ 65.7 เชื่อว่าภาวะหมดประจำเดือนเป็นการเปลี่ยนแปลงของร่างกายตามธรรมชาติ ถึงแม้บางคนอาจ
จำเป็นต้องได้รับการรักษา ร้อยละ 53.9 เป็นผู้ที่กำลังได้รับฮอร์โมนทดแทน โดยระยะเวลาเฉลี่ยของการใช้ฮอร์โมนของผู้ตอบ-
แบบสอบถามในกลุ่มนี้ประมาณ 4.70 ± 3.36 ปี ข้อบ่งชี้ในการใช้ฮอร์โมนทดแทนที่พบบ่อยที่สุดได้แก่ ภาวะกระดูกพรุน
อาการร้อนวูบวาบ และอาการช่องคลอดแห้ง อาการข้างเคียงที่พบบ่อยที่สุดในกลุ่มที่กำลังใช้ฮอร์โมนทดแทนได้แก่ เจ็บคัดหน้าอก
ปวดศีรษะ และเลือดออกทางช่องคลอด ร้อยละ 43.2 ในกลุ่มที่กำลังใช้ฮอร์โมนทดแทน ต้องการเปลี่ยนการรักษาไปจากการ
ใช้ฮอร์โมน ร้อยละ 95.4 ตัดสินใจเลือกการรักษาจากคำแนะนำทางการแพทย์ ร้อยละ 62.0-74.7 ของผู้ตอบแบบสอบถาม
ทั้งหมด รายงานว่า ยังไม่ได้รับข้อมูลเกี่ยวกับภาวะหมดประจำเดือนและฮอร์โมนทดแทนอย่างเพียงพอและชัดเจน

สรุป : จากรายงานนี้พบว่า สตรีที่ตอบแบบสอบถามส่วนใหญ่เชื่อว่า ภาวะหมดประจำเดือนเป็นการเปลี่ยนแปลงตามธรรม-
ชาติ แต่บางรายจำเป็นต้องได้รับการรักษา เหตุผลที่ใช้ฮอร์โมนทดแทนที่พบบ่อยได้แก่ ภาวะกระดูกพรุน อาการร้อนวูบวาบ
อาการช่องคลอดแห้ง เกือบครึ่งหนึ่งของผู้ที่กำลังใช้ฮอร์โมนทดแทนต้องการเปลี่ยนการรักษา ส่วนใหญ่ของผู้ตอบแบบสอบถาม
ตัดสินใจเลือกวิธีการรักษาจากคำแนะนำของแพทย์

คำสำคัญ : ภาวะหมดประจำเดือน, ฮอร์โมนทดแทน, ทัศนคติ, ความยอมรับ

นิมิต เทชไกรชนะ, กิตติศักดิ์ วิลาวรรณ, วีรวัฒน์ วิภาตวิทย์ และคณะ
